

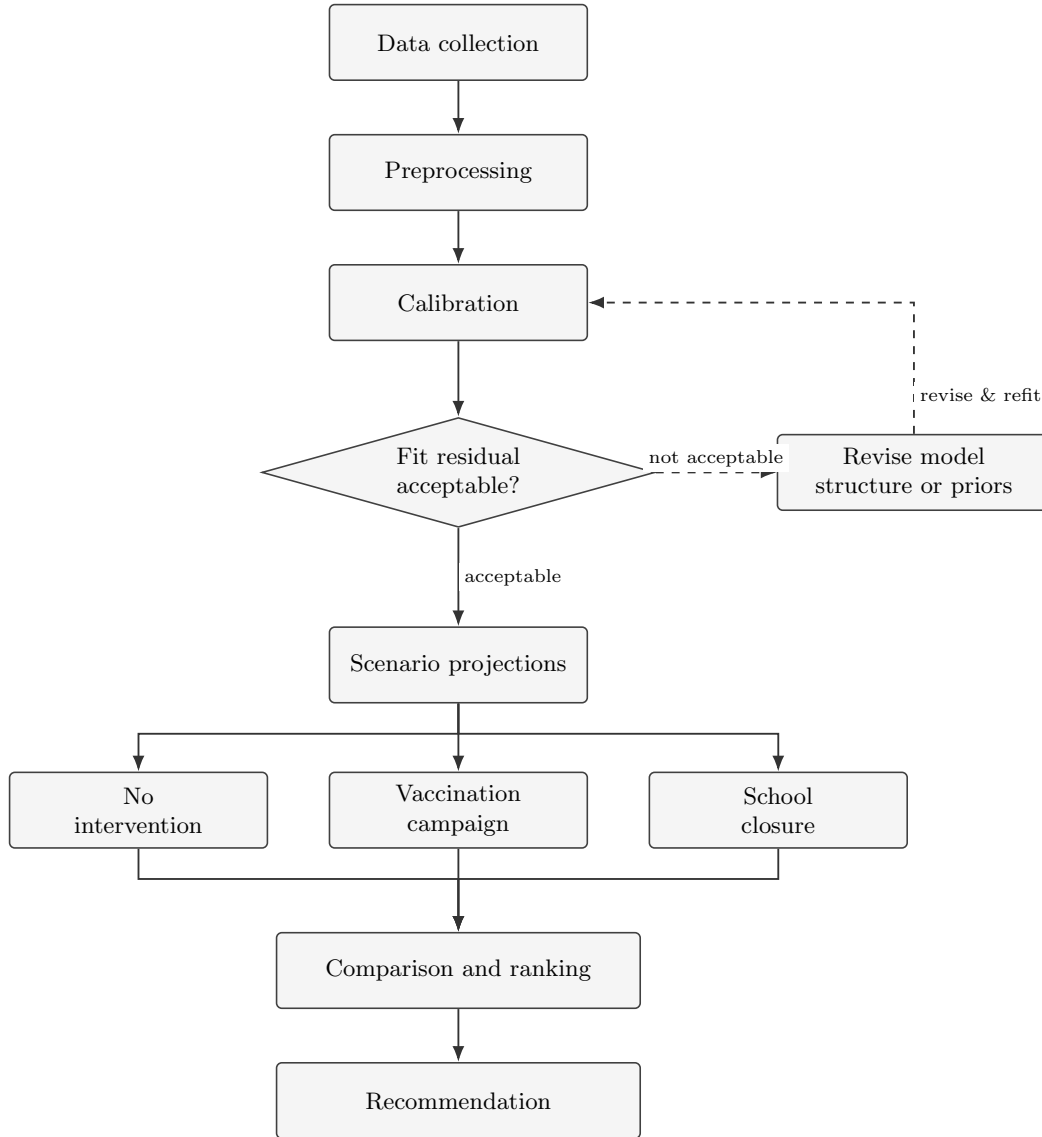

Figure 1: Modelling workflow of the epidemic-control study. Weekly case counts, mobility traces and vaccination coverage are collected for the study city and aligned onto a common weekly grid, and a compartmental transmission model is calibrated to the aligned data. If the fit residual is unacceptable, the model structure or the priors are revised and calibration is repeated; otherwise the calibrated model is projected forward under three policies (no intervention, a vaccination campaign, and school closure). The three projections are compared and ranked, and the ranking is summarised as the paper’s recommendation.
